1 Symmetric Groups

1.1 Symmetric Groups

Definition 1.1 (Permutation)

A *permutation* of a set S is a bijective map p from S to itself. That is, $p: S \rightarrow S$.

Definition 1.2

The set of all permutations of the indices $\{1, 2, \dots, n\}$ is called the *symmetric group* on n elements, denoted by S_n .

Definition 1.3

Let X be a set. The set of all permutations of X is called the *symmetric group* on X , denoted by S_X .

Proposition 1.4

(S_n, \circ) and (S_X, \circ) are isomorphic groups.

1.2 Permutation Matrices

A *permutation matrix* is associated to any permutation.

Definition 1.5 (Permutation matrix)

An $n \times n$ permutation matrix is an $n \times n$ matrix P whose columns are a permutation of the standard basis e_1, e_2, \dots, e_n .

Proposition 1.6

Let S_n'' denote the set of all $n \times n$ permutation matrices. Let \times denote matrix multiplication. Then, (S_n'', \times) is a group and is isomorphic to (S_n, \circ) .

1.3 Cyclic Notations

We can express permutations as a product of disjoint cycles. This notation is called the *cyclic notation* and is more compact compared to the tabular notation.

Example 1.7

The permutation $p = (34)(12) \in S_4$ contains the following disjoint cycles: $1 \mapsto 2$, $2 \mapsto 1$, $3 \mapsto 4$, $4 \mapsto 3$, and $5 \mapsto 5$.

In fact, we can think of a cycle as a permutation.

Definition 1.8

Consider a permutation $p \in S_n$ with a cycle $(x_1 x_2 \cdots x_r)$. The cycle is a permutation $h \in S_n$ such that $h(x_1) = x_2, h(x_2) = x_3, \dots, h(x_r) = h(x_1)$ and $h(y) = y$ for any y not in the cycle.

Then, a product of disjoint cycles simply refers to the composition of the corresponding permutations.

Proposition 1.9

Every permutation can be factorized into a product of disjoint cycles. The factorization is unique up to an ordering of the product of cycles.

1.4 Transpositions

Definition 1.10

A *transposition* is a cycle of the form $h = (ij)$.

Proposition 1.11

Any cycle can be written as a product of transpositions.

Proof sketch. Let $h = (i_1, \dots, i_r)$. Then, $(i_1 i_r)(i_1 i_{r-1}) \cdots (i_1 i_2)$ is an equivalent permutation. \square

Since any permutation can be expressed as a product of disjoint cycles, we can also express any permutation as a product of transpositions.

Proposition 1.12

Every permutation can be expressed as a product of transpositions.

1.5 The Sign Character

Lemma 1.13

For any permutation matrices F and H in S_n'' , we have $\det(FH) = \det(F)\det(H)$ and $\det(F) = \pm 1$.

Since permutations in S_n are isomorphic to permutation matrices in S_n'' , observe the *sign* of a permutation is equivalent to the determinant of its corresponding permutation matrix.

Example 1.14 (Sign of a Permutation)

Let p be a permutation in S_n and φ be an isomorphism between S_n and S_n'' . Then, the *sign* of p is $\text{sgn}(p) = \det(\varphi(p))$.

However, the determinant of a matrix is typically defined in terms of its sign, so we define the sign in an alternative fashion.

Definition 1.15

Let $\mathbf{x} = (x_1, x_2, \dots, x_n)$ be n variables.

Define $P(\mathbf{x}) = P(x_1, \dots, x_n) = \prod_{1 \leq i < j \leq n} (x_i - x_j)$.

Then, for each permutation $f \in S_n$, define $P_f(x_1, \dots, x_n) = P(x_{f(1)}, x_{f(2)}, \dots, x_{f(n)}) = \prod_{1 \leq i < j \leq n} (x_{f(i)} - x_{f(j)})$.

Proposition 1.16

For any permutation $f \in S_n$, $P_f(x_1, \dots, x_n) = \pm P(x_1, \dots, x_n)$. We call the sign of P_f the *sign character* of f .

Proposition 1.17

For any permutations $f, h \in S_n$, $\text{sgn}(f \circ h) = \text{sgn}(f)\text{sgn}(h)$.

Definition 1.18

A permutation $f \in S_n$ is *even* if $\text{sgn}(f) = 1$. Otherwise, it is *odd*.

Theorem 1.19

Let $f \in S_n$ be a permutation. f is even iff f is a product of an even number of transpositions.

Proposition 1.20

The set of all even permutations in S_n is a subgroup of S_n .
